**Abstract.** We present a capability calculus for checking partial confluence of channel-communicating concurrent processes. Our approach automatically detects more programs to be partially confluent than previous approaches, and is able to handle a mix of different kinds of communication channels, including shared reference cells.

#### 1 Introduction

Deterministic programs are easier to debug and verify than non-deterministic programs, both for testing (or simulation) and for formal methods. However, sometimes programs are written as communicating concurrent processes, for speed or for ease of programming, and therefore possibly non-deterministic. In this paper, we present a system that can automatically detect more programs to be deterministic than previous methods [7, 10, 8, 9, 5]. Our system is able to handle programs communicating via a mix of different kinds of channels: rendezvous, output buffered, input buffered, and shared reference cells. Section 3.2 shows a few examples that can be checked by our system: producer consumer, token ring, and barrier synchronization.

We cast our system as a capability calculus [4]. The capability calculus was originally proposed as a framework for reasoning about resources in sequential computation, but has recently been extended to reason about determinism in concurrent programs [3,11]. However, these systems can only reason about synchronization at join points, and therefore cannot verify determinism of channel-communicating processes. This paper extends the capability calculus to reason about synchronization due to channel communications. A key insight comes from our previous work [11] which showed that confluence can be ensured in a principled way from ordering dependencies between the side effects; dependencies are enforced by finding a flow assignment (which can be interpreted as fractional capabilities [3]) in the dependence graph.

#### 2 Preliminaries

We focus on the simple concurrent language shown in Figure 1. A program, p, is a parallel composition of finitely many processes. A process, s, is a sequential

<sup>\*</sup> This research was supported in part by NSF Grant No. CCR-0326577.

```
p ::= s_1||s_2||\dots||s_n \ (program)
                                                                               (sequence)
                                               s ::= s_1; s_2
                        (channel)
                                                     if e then s_1 else s_2 (branch)
                        (local variable)
                                                      \mathtt{while}\; e\; \mathtt{do}\; s
                                                                               (loop)
                        (integer constant)
                                                      skip
                                                                               (skip)
      e_1 op e_2
                        (integer operation)
                                                      x := e
                                                                               (assignment)
                                                      !(e_1,e_2)
                                                                               (write channel)
                                                      ?(e,x)
                                                                               (read channel)
```

Fig. 1. The syntax of the small concurrent language.

statement consisting of the usual imperative features as well as channel communication operations. Here,  $!(e_1, e_2)$  means writing the value of  $e_2$  to the channel  $e_1$ , and ?(e, x) means storing the value read from the channel e to the variable x. The variables are process-local, and so the only means of communication are channel reads and writes. We use meta-variables x, y, z, etc. for variables and c, d, etc. for channels.

The language cannot dynamically create channels or spawn new processes, but these restrictions are imposed only to keep the main presentation to the novel features of the system. Section 3.3 shows that techniques similar to previous works in the capability calculus can be used to handle dynamic channels and processes.

#### 2.1 Channel Kinds

The literature on concurrency includes several forms of channels with distinct semantics. We introduce these channel kinds and show how they affect determinism.

If c and d are rendezvous channels, then the following program is deterministic<sup>3</sup> because (x, y) = (1, 2) when the process terminates:

$$!(c,1); !(d,2) || !(d,3); ?(c,x) || ?(d,y); ?(d,y)$$

The same program is non-deterministic if c is output buffered because !(c,1) does not need to wait for the reader ?(c,x), and therefore (x,y) could be (1,2) or (1,3).

While all the processes share one output buffer per channel, each process has its own input buffer per channel. Therefore, !(c,1); !(c,2) || ?(c,x) || ?(c,y) is deterministic if c is input buffered but not if c is output buffered or rendezvous. Input buffered channels are the basis of Kahn process networks [7].

We also consider a buffered channel whose buffer is overwritten by every write but never modified by a read. Such a channel is equivalent to a reference cell. If c is a reference cell, !(c,1); !(c,2) || ?(c,x) is not deterministic because !(c,2) may or may-not overwrite 1 in the buffer before ?(c,x) reads the buffer.

<sup>&</sup>lt;sup>3</sup> Here, we use the term informally. Determinism is formally defined in Section 2.2.

$$\frac{(S(i), e) \Downarrow n \qquad n \neq 0}{(B, S, i.(\text{if } e \text{ then } s_1 \text{ else } s_2); s||p) \to (B, S, i.s_1; s||p)} \text{ IF1}$$

$$\frac{(S(i), e) \Downarrow 0}{(B, S, i.(\text{if } e \text{ then } s_1 \text{ else } s_2); s||p) \to (B, S, i.s_2; s||p)} \text{ IF2}$$

$$\frac{(S(i), e) \Downarrow n \qquad n \neq 0}{(B, S, i.(\text{while } e \text{ do } s_1); s||p) \to (B, S, i.s_1; (\text{while } e \text{ do } s_1); s||p)} \text{ WHILE1}$$

$$\frac{(S(i), e) \Downarrow 0}{(B, S, i.(\text{while } e \text{ do } s_1); s||p) \to (B, S, i.s||p)} \text{ WHILE2}$$

$$\frac{(S(i), e) \Downarrow e' \qquad S' = S[i \mapsto S(i) :: (x, e')]}{(B, S, i.x := e; s||p) \to (B, S', i.s||p)} \text{ ASSIGN}$$

$$\frac{(S(i), e_1) \Downarrow c \qquad (S(i), e_2) \Downarrow e'_2 \qquad (S(j), e_3) \Downarrow c \\ \neg buffered(c) \qquad S' = S[j \mapsto S(j) :: (x, e'_2)]}{(B, S, i.!(e_1, e_2); s_1||j.?(e_3, x); s_2||p) \to (B, S', i.s_1||j.s_2||p)} \text{ UNBUF}$$

$$\frac{(S(i), e_1) \Downarrow c \qquad (S(i), e_2) \Downarrow e'_2 \qquad buffered(c) \qquad B' = B.write(c, e'_2)}{(B, S, i.!(e_1, e_2); s||p) \to (B', S, i.s||p)} \text{ BUF1}$$

$$\frac{(S(i), e) \Downarrow c \qquad buffered(c)}{(B', e') = B.read(c, i) \qquad S' = S[i \mapsto S(i) :: (x, e')]} \text{ BUF2}$$

Fig. 2. The operational semantics of the small concurrent language.

The program is deterministic if c is any other channel kind. On the other hand, !(c,1); !(c,2); !(d,3); ?(c,x) || ?(d,x); ?(c,y) is deterministic if c is a reference cell and d is rendezvous because both reads of c happen after !(c,2) overwrites the buffer. But the program is not deterministic if c is output buffered.

#### 2.2 Operational Semantics

The operational semantics of the language is defined as a series of reductions from states to states. A state is represented by the triple (B, S, p) where B is a buffer, S is a store, and p is a program such that each concurrent process in p is indexed by a process number, i.e.,  $p := 1.s_1||2.s_2||\dots||n.s_n$ . Indexes are used to connect a process to its input buffer and its store.

A store is a mapping from process indexes to histories of assignments where a *history* is a sequence of pairs (x, e), meaning e was assigned to x. We use meta-variables h, h', etc. for histories. Let :: be append. A lookup in a history is defined as: (h :: (x, e))(x) = e and (h :: (y, e))(x) = h(x) if  $y \neq x$ . We use history instead of memory for the purpose of defining determinism.

$$B.write(c,e) = \begin{cases} B[c \mapsto enq(B(c),e)] & \text{if } c \text{ is output buffered} \\ B[c \mapsto \langle enq(q_1,e),\ldots,enq(q_n,e)\rangle] & \text{if } c \text{ is input buffered} \\ \text{where } B(c) = \langle q_1,\ldots,q_n\rangle & \text{if } c \text{ is a reference cell} \end{cases}$$
 
$$B[c \mapsto e] & \text{if } c \text{ is a reference cell}$$
 
$$Where B(c) = q \text{ and } (q',e) = deq(q) & \text{if } c \text{ is output buffered} \\ (B[c \mapsto \langle q_1,\ldots,q_i',\ldots,q_n\rangle],e) & \text{if } c \text{ is input buffered} \\ (B[c \mapsto \langle q_1,\ldots,q_i',\ldots,q_i,\ldots,q_n\rangle],e) & \text{if } c \text{ is input buffered} \\ (q_i',e) = deq(q_i) & \text{if } c \text{ is a reference cell} \end{cases}$$

Fig. 3. Buffer operations.

Expressions are evaluated entirely locally. The semantics of expressions are defined as:  $(h, c) \Downarrow c$ ,  $(h, x) \Downarrow h(x)$ ,  $(h, n) \Downarrow n$ , and  $(h, e_1 \ op \ e_2) \Downarrow e'_1 \ op \ e'_2$  if  $(h, e_1) \Downarrow e'_1$  and  $(h, e_2) \Downarrow e'_2$ .

Figure 2 shows the reduction rules. Programs are equivalent up to re-ordering of parallel processes, e.g.,  $p_1||p_2=p_2||p_1$ . If p is an empty program (i.e., p contains 0 processes), then p'||p=p'. Also, we let s=s; skip = skip; s. Note that the rules only reduce the left-most processes, and so we rely on process re-ordering to reduce other processes. The rules IF1, IF2, WHILE1, and WHILE2 do not involve channel communication and are self-explanatory. AS-SIGN is also a process-local reduction because variables are local. Here,  $S[i\mapsto h]$  means  $\{j\mapsto S(j)\mid j\neq i\land j\in dom(S)\}\cup\{i\mapsto h\}$ . We use the same notation for other mappings.

**UNBUF** handles communication over rendezvous channels. The predicate  $\neg buffered(c)$  says c is unbuffered (and therefore rendezvous). Note that the written value  $e_2'$  is immediately transmitted to the reader. **BUF1** and **BUF2** handle communication over buffered channels, which include output buffered channels, input buffered channels, and reference cells. The predicate buffered(c) says that c is a buffered channel. We write  $B.write(c, e_2')$  for the buffer B after  $e_2'$  is written to the channel c, and B.read(c, i) for the pair (B', e') where e' is the value process i read from channel c and B' is the buffer after the read.

Formally, a buffer B is a mapping from channels to buffer contents. If c is a rendezvous channel, then B(c) = nil indicating that c is not buffered. If c is output buffered, then B(c) = q where q is a FIFO queue of values. If c is input buffered, then  $B(c) = \langle q_1, q_2, \ldots, q_n \rangle$ , i.e., a sequence of FIFO queues where each  $q_i$  represents the buffer content for process i. If c is a reference cell, then B(c) = e for some value e. Let enq(q,e) be q after e is enqueued. Let deq(q) be the pair (q',e) where q' is q after e is dequeued. Buffer writes and reads are defined as shown in Figure 3. Note that B.read(c,i) and B.write(c,e) are undefined if c is rendezvous.

We write  $P \to^* Q$  for 0 or more reduction steps from P to Q. We define partial confluence and determinism.

**Definition 1.** Let Y be a set of channels. We say that P is partially confluent with respect to Y if for any  $P \to^* P_1$  communicating only over channels in Y, and for any  $P \to^* P_2$ , there exists a state Q such that  $P_2 \to^* Q$  communicating only over channels in Y and  $P_1 \to^* Q$ .

**Definition 2.** Let Y be a set of channels. We say that P is deterministic with respect to Y if for each process index i, there exists a (possibly infinite) sequence  $h_i$  such that for any  $P \to^* (B, S, p)$  that communicates only over channels in Y, S(i) is a prefix of  $h_i$ .

Determinism implies that for any single process, interaction with the rest of the program is deterministic. Determinism and partial confluence are related in the following way.

**Lemma 1.** If P is partially confluent with respect to Y then P is deterministic with respect to Y.

Note that the definitions are sufficient for programs interacting with the environment because an environment can be modeled as a process using integer operators with unknown (but deterministic) semantics.

### 3 Calculus of Capabilities

We now present a capability calculus for ensuring partial confluence. While capability calculi are typically presented as a type system in the literature, we take a different approach and present the capability calculus as a dynamic system. We then construct a type system to statically reason about the dynamic capability calculus. This approach allows us to distinguish approximations due to the type abstraction from approximations inherent in the capability concept. (We have taken a similar approach in previous work [11].)

We informally describe the general idea. To simplify matters, we begin this initial discussion with rendezvous channels and total confluence. Given a program, the goal is to ensure that for each channel c, at most one process can write c and at most one process can read c at any point in time. To this end, we introduce capabilities r(c) and w(c) such that a process needs r(c) to read from c and w(c) to write to c. Capabilities are distributed to the processes at the start of the program and are not allowed be duplicated.

Recall the following confluent program from Section 2:

$$1.!(c,1);!(d,2) || 2.!(d,3);?(c,x) || 3.?(d,y);?(d,y)$$

Note that for both c and d, at most one process can read and at most one process can write at any point in time. However, because both process 1 and process 2 write to d, they must somehow share w(d). A novel feature of our

capability calculus is the ability to pass capabilities between processes. The idea is to let capabilities be passed when the two processes synchronize, i.e., when the processes communicate over a channel. In our example, we let process 2 have w(d) at the start of the program. Then, when process 1 and process 2 communicate over c, we pass w(d) from process 2 to process 1 so that process 1 can write to d.

An important observation is that capability passing works in this example because !(d,3) is guaranteed to occur before the communication on c due to c being rendezvous. If c is buffered (recall that the program is not confluent in this case), then !(c,1) may occur before !(d,3). Therefore, process 1 cannot obtain w(d) from process 2 when c is written because process 2 may still need w(d) to write on d. In general, for a buffered channel, while the read is guaranteed to occur after the write, there is no ordering dependency in the other direction, i.e., from the read to the write. Therefore, capabilities can be passed from the writer to the reader but not vice versa, whereas capabilities can be passed in both directions at communication over a rendezvous channel.

Special care is needed for reference cells. If c is a reference cell, the program 1.!(c,1); !(c,2)||2.?(c,x) is not deterministic although process 1 is the only writer and process 2 is the only reader. We use *fractional capabilities* [3,11] such that a read capability is a fraction of the write capability. Capabilities can be split into multiple fractions, which allows concurrent reads on the same reference cell, but must be re-assembled to form the write capability. Fractional capabilities can be passed between processes in the same way as other capabilities. Recall the following confluent program from Section 2 where c is a reference cell and d is rendezvous:

$$1.!(c,1); !(c,2); !(d,3); ?(c,x) || 2.?(d,x); ?(c,y)$$

Process 1 must start with the capability to write c. Because both processes read from c after communicating over d, we split the capability for c such that one half of the capability stays in process 1 and the other half is passed to process 2 via d. As a result, both processes obtain the capability to read from c. We have shown previously that fractional capabilities can be derived in a principled way from ordering dependencies [11].

We now formally present our capability calculus. Let

```
Capabilities = \{w(c), r(c) \mid c \text{ is rendezvous or output buffered}\}\
 \cup \{w(c) \mid c \text{ is input buffered}\} \cup \{w(c) \mid c \text{ is a reference cell}\}\
```

A capability set C is a function from **Capabilities** to rational numbers in the range [0,1]. If c is rendezvous, output buffered, or input buffered, C(w(c)) = 1 (resp. C(r(c)) = 1) means that the capability to write (resp. read) c is in C. Read capabilities are not needed for input buffered channels because each process has its own buffer. For reference cells, C(w(c)) = 1 means that the capability to write is in C, whereas C(w(c)) > 0 means that the capability to read is in C.

$$\frac{(S(i),e) \Downarrow n}{(X,B,S,i.C.(\text{if }e \text{ then }s_1 \text{ else }s_2);s||p) \rightarrow (X,B,S,i.C.s_1;s||p)} \text{ IF1'}$$

$$\frac{(S(i),e) \Downarrow 0}{(X,B,S,i.C.(\text{if }e \text{ then }s_1 \text{ else }s_2);s||p) \rightarrow (X,B,S,i.C.s_2;s||p)} \text{ IF2'}$$

$$\frac{(S(i),e) \Downarrow n}{(X,B,S,i.C.(\text{while }e \text{ do }s_1);s||p)} \text{ WHILE1'}$$

$$\frac{(S(i),e) \Downarrow n}{\rightarrow (X,B,S,i.C.s_1;(\text{while }e \text{ do }s_1);s||p)} \text{ WHILE2'}$$

$$\frac{(S(i),e) \Downarrow 0}{(X,B,S,i.C.(\text{while }e \text{ do }s_1);s||p) \rightarrow (X,B,S,i.C.s||p)} \text{ WHILE2'}$$

$$\frac{(S(i),e) \Downarrow e' \qquad S' = S[i \mapsto S(i) :: (x,e')]}{(X,B,S,i.C.x := e;s||p) \rightarrow (X,B,S',i.C.s||p)} \text{ ASSIGN'}$$

Fig. 4. The capability calculus: sequential reductions.

To summarize, we define the following predicates:

$$\begin{aligned} hasWcap(C,c) &\Leftrightarrow C(w(c)) = 1 \\ hasRcap(C,c) &\Leftrightarrow \begin{cases} C(r(c)) = 1 & \text{if $c$ is rendezvous or output buffered} \\ true & \text{if $c$ is input buffered} \\ C(w(c)) > 0 & \text{if $c$ is reference cell} \end{aligned}$$

To denote capability merging and splitting, we define:

$$C_1 + C_2 = \{ cap \mapsto C_1(cap) + C_2(cap) \mid cap \in \mathbf{Capabilities} \}$$

We define  $C_1 - C_2 = C_3$  if  $C_1 = C_3 + C_2$ . (We avoid negative capabilities.)

Figure 4 and Figure 5 show the reduction rules of the capability calculus. The reduction rules (technically, labeled transition rules) are similar to those of operational semantics with the following differences.

Each concurrent process is prefixed by a capability set C representing the current capabilities held by the process. The rules in Figure 4 do not utilize capabilities (i.e., capabilities are only passed sequentially) and are self-explanatory. Figure 5 shows how capabilities are utilized at communication points. **UNBUF'** sends capabilities C from the writer process to the reader process and sends capabilities C' from the reader process to the writer process. **UNBUF'** checks whether the right capabilities are present by  $hasWcap(C_i, c) \wedge hasRcap(C_j, c)$ . The label  $\ell$  records whether the check succeeds. Because we are interested in partial confluence with respect to some set Y of channels, we only check the capabilities if  $c \in Y$ . To this end, the predicate confch(c) parametrizes the system so that confch(c) iff  $c \in Y$ .

 $\mathbf{BUF1'}$  and  $\mathbf{BUF2'}$  handle buffered communication. Recall that the writer can pass capabilities to the reader.  $\mathbf{BUF1'}$  takes capabilities C' from the writer process and store them in X.  $\mathbf{BUF2'}$  takes capabilities C' from X and give

$$(S(i), e_1) \Downarrow c \qquad (S(i), e_2) \Downarrow e'_2 \qquad (S(j), e_3) \Downarrow c$$

$$\neg buffered(c) \qquad S' = S[j \mapsto S(j) :: (x, e'_2)]$$

$$\ell = (confch(c) \Rightarrow (hasWcap(C_i, c) \land hasRcap(C_j, c))) \qquad \textbf{UNBUF'}$$

$$(X, B, S, i.C_i.!(e_1, e_2); s_1 || j.C_j?(e_3, x); s_2 || p)$$

$$\stackrel{\ell}{\rightarrow} (X, B, S', i.(C_i - C + C').s_1 || j.(C_j + C - C').s_2 || p)$$

$$(S(i), e_1) \Downarrow c \qquad (S(i), e_2) \Downarrow e'_2 \qquad buffered(c)$$

$$B' = B.write(c, e'_2) \qquad \ell = (confch(c) \Rightarrow hasWcap(C, c))$$

$$(X, B, S, i.C.!(e_1, e_2); s || p) \stackrel{\ell}{\rightarrow} (X[c \mapsto X(c) + C'], B', S, i.(C - C').s || p)$$

$$(S(i), e) \Downarrow c \qquad buffered(c) \qquad (B', e') = B.read(c, i)$$

$$S' = S[i \mapsto S(i) :: (x, e')] \qquad \ell = (confch(c) \Rightarrow \neg hasRcap(C, c))$$

$$(X, B, S, i.C.?(e, x); s || p) \stackrel{\ell}{\rightarrow} (X[c \mapsto X(c) - C'], B', S', i.(C + C').s || p)$$

$$BUF2'$$

Fig. 5. The capability calculus: communication reductions.

them to the reader process. The mapping X from channels to capability sets maintains the capabilities stored in each channel.

We now formally state when our capability calculus guarantees partial confluence. Let  $erase((X, B, S, 1.C_1.s_1||...||n.C_n.s_n)) = (B, S, 1.s_1||...||n.s_n)$ , i.e., erase() erases all capability information from the state. We use meta-variables P, Q, R, etc. for states in the operational semantics and underlined meta-variables  $\underline{P}$ , Q,  $\underline{R}$ , etc. for states in the capability calculus.

A well-formed state is a state in the capability calculus that does not carry duplicated capabilities. More formally,

**Definition 3.** Let 
$$\underline{P} = (X, B, S, 1.C_1.s_1 || \dots || n.C_n.s_n)$$
. Let  $C = \sum_{i=1}^n C_i + \sum_{c \in dom(X)} X(c)$ . We say  $\underline{P}$  is well-formed if for all  $cap \in dom(C)$ ,  $C(cap) = 1$ .

We define capability-respecting states. Informally,  $\underline{P}$  is capability respecting with respect to a set of channels Y if for any sequence of reductions from erase(P), there exists a strategy to pass capabilities between the processes such that every communication over the channels in Y occurs under the appropriate capabilities. More formally,

**Definition 4.** Let Y be a set of channels and let  $confch(c) \Leftrightarrow c \in Y$ . Let M be a set of states in the capability calculus. M is said to be capability-respecting with respect to Y if for any  $P \in M$ ,

- $-\underline{P}$  is well-formed, and for any state Q such that  $erase(\underline{P}) \rightarrow Q$ , there exists  $\underline{Q} \in M$  such that,  $erase(Q) = Q, \underline{P} \xrightarrow{\ell} Q$ , and if  $\ell$  is not empty then  $\ell = true$ .

We now state the main claim of this section.

**Theorem 1.** Let P be a state. Suppose there exists M such that M is capabilityrespecting with respect to Y and there exists  $\underline{P} \in M$  such that  $erase(\underline{P}) = P$ . Then P is partially confluent with respect to Y.

#### 3.1 Static Checking of Capabilities

Theorem 1 tells us that to ensure that P is partially confluent, it is sufficient to find a capability-respecting set containing some  $\underline{P}$  such that  $erase(\underline{P}) = P$ . <sup>4</sup> Ideally, we would like to use the largest capability-respecting set, but such a set is not recursive (because it is reducible from the halting problem). Instead, we use a type system to compute a safe approximation of the set.

We define four kinds of channel types, one for each channel kind.

$$\tau ::= ch(\rho, \tau, \Psi_1, \Psi_2) \qquad (rendezvous)$$

$$\mid ch(\rho, \tau, \Psi) \qquad (output \ buffered)$$

$$\mid ch(\rho, \tau, \langle \Psi_1, \dots, \Psi_n \rangle) \ (input \ buffered)$$

$$\mid ch(\rho, \tau) \qquad (reference \ cell)$$

$$\mid int \qquad (integers)$$

Meta-variables  $\rho$ ,  $\rho'$ , etc. are channel handles. Let **Handles** be the set of channel handles. Let **StaticCapabilities** =  $\{w(\rho), r(\rho) \mid \rho \in \mathbf{Handles}\}$ . Meta-variables  $\Psi$ ,  $\Psi'$ , etc. are mappings from **StaticCapabilities** to [0,1]. We call such a mapping a static capability set. The rendezvous channel type can be read as follows: the channel communicates values of type  $\tau$ , any writer of the channel sends capabilities  $\Psi_1$ , and any reader of the channel sends capabilities, only one static capability set,  $\Psi$ , is present in its type. For an input buffered channel, the sequence  $\langle \Psi_1, \ldots, \Psi_n \rangle$  lists capabilities such that each process i gets  $\Psi_i$  from a read. Because a value stored in a reference cell may be read arbitrary many times, our type system cannot statically reason about processes passing capabilities through reference cells, and so a reference cell type does not carry any static capability set.

Additions and subtractions of static capabilities are analogous to those of (actual) capabilities:

$$\begin{array}{l} \varPsi_1 + \varPsi_2 = \{\mathit{cap} \mapsto \varPsi_1(\mathit{cap}) + \varPsi_2(\mathit{cap}) \mid \mathit{cap} \in \mathbf{StaticCapabilities}\} \\ \varPsi_1 - \varPsi_2 = \varPsi_3 \quad \text{if } \varPsi_1 = \varPsi_3 + \varPsi_2 \end{array}$$

We say  $\Psi_1 \geq \Psi_2$  if there exists  $\Psi_3$  such that  $\Psi_1 = \Psi_2 + \Psi_3$ .

For channel type  $\tau$ ,  $hdl(\tau)$  is the handle of the channel, and  $valtype(\tau)$  is the type of the communicated value. That is,  $hdl(ch(\rho, \ldots)) = \rho$  and  $valtype(ch(\rho, \tau, \ldots)) = \tau$ . Also,  $writeSend(\tau)$  (resp.  $readSend(\tau)$ ) is the set of capabilities sent by a writer (resp. reader) of the channel. More formally,

$$writeSend(ch(\rho, \tau, \Psi_1, \Psi_2)) = \Psi_1$$

$$writeSend(ch(\rho, \tau, \Psi)) = \Psi$$

$$writeSend(ch(\rho, \tau, \langle \Psi_1, \dots, \Psi_n \rangle)) = \sum_{i=1}^n \Psi_i$$

$$writeSend(ch(\rho, \tau)) = 0$$

$$readSend(\tau) = \begin{cases} \Psi_2 & \text{if } \tau = ch(\rho, \tau', \Psi_1, \Psi_2) \\ 0 & \text{otherwise} \end{cases}$$

<sup>&</sup>lt;sup>4</sup> It is not a necessary condition, however. For example, !(c,1)||!(c,1)||?(c,x)||?(c,x) is confluent but does not satisfy the condition.

$$\frac{\Gamma, i, \Psi \vdash s_1 : \Psi_1 \quad \Gamma, i, \Psi_1 \vdash s_2 : \Psi_2}{\Gamma, i, \Psi \vdash s_1 : s_2 : \Psi_2} \quad \mathbf{SEQ}$$

$$\frac{\Gamma \vdash e : int \quad \Gamma, i, \Psi \vdash s_1 : \Psi_1 \quad \Gamma, i, \Psi \vdash s_2 : \Psi_2 \quad \Psi_1 \geq \Psi_3 \quad \Psi_2 \geq \Psi_3}{\Gamma, i, \Psi \vdash \text{ if } e \text{ then } s_1 \text{ else } s_2 : \Psi_3} \quad \mathbf{IF}$$

$$\frac{\Gamma \vdash e : int \quad \Gamma, i, \Psi_1 \vdash s : \Psi_2 \quad \Psi_2 \geq \Psi_1 \quad \Psi \geq \Psi_1}{\Gamma, i, \Psi \vdash \text{ while } e \text{ do } s : \Psi_2} \quad \mathbf{WHILE}$$

$$\frac{\Gamma \vdash e : \Gamma(x)}{\Gamma, i, \Psi \vdash \text{ skip } : \Psi} \quad \mathbf{SKIP} \quad \frac{\Gamma \vdash e : \Gamma(x)}{\Gamma, i, \Psi \vdash x := e : \Psi} \quad \mathbf{ASSIGN}$$

$$\frac{\Gamma \vdash e_1 : \tau \quad \Gamma \vdash e_2 : valtype(\tau) \quad confch(\tau, \Gamma) \Rightarrow hasWcap(\Psi, \tau)}{\Gamma, i, \Psi \vdash ! (e_1, e_2) : \Psi - writeSend(\tau) + writeRecv(\tau)} \quad \mathbf{WRITE}$$

$$\frac{\Gamma \vdash e : \tau \quad \Gamma(x) = valtype(\tau) \quad confch(\tau, \Gamma) \Rightarrow hasRcap(\Psi, \tau)}{\Gamma, i, \Psi \vdash ? (e, x) : \Psi - readSend(\tau) + readRecv(\tau, i)} \quad \mathbf{READ}$$

Fig. 6. Type checking rules.

(0 is the constant zero function  $\lambda x.0.$ ) Similarly,  $writeRecv(\tau)$  (resp.  $readRecv(\tau, i)$ ) is the set of capabilities received by the writer (resp. the reader process i):

$$\begin{aligned} \textit{writeRecv}(\tau) &= \textit{readSend}(\tau) \\ \textit{readRecv}(\tau, i) &= \begin{cases} \Psi_i & \text{if } \tau = \textit{ch}(\rho, \tau, \langle \Psi_1, \dots, \Psi_n \rangle) \\ \textit{writeSend}(\tau) & \text{otherwise} \end{cases} \end{aligned}$$

Note that the writer of the input buffered channel  $ch(\rho, \tau, \langle \Psi_1, \dots, \Psi_n \rangle)$  must be able to send the sum of all capabilities to be received by each process (i.e.,  $\sum_{i=1}^{n} \Psi_i$ ), whereas the reader receives only its own share (i.e.,  $\Psi_i$ ).

For channel type  $\tau$ ,  $hasWcap(\Psi, \tau)$  and  $hasRcap(\Psi, \tau)$  are the static analog of hasWcap(C, c) and hasRcap(C, c). More formally,

$$\begin{split} hasWcap(\Psi,\tau) &\Leftrightarrow \varPsi(w(hdl(\tau))) = 1 \\ hasRcap(\Psi,\tau) &\Leftrightarrow \begin{cases} \varPsi(r(hdl(\tau))) = 1 & \text{if } \tau \text{ is rendezvous or output buffered} \\ true & \text{if } \tau \text{ is input buffered} \\ \varPsi(w(hdl(\tau))) > 0 & \text{if } \tau \text{ is reference cell} \end{cases} \end{split}$$

A type environment  $\Gamma$  is a mapping from channels and variables to types such that for each channel c and d,

- the channel type kind of  $\Gamma(c)$  coincides with the channel kind of c, and
- if  $c \neq d$  then  $hdl(\Gamma(c)) \neq hdl(\Gamma(d))$ , i.e., each handle  $\rho$  uniquely identifies a channel. (Section 3.3 discusses a way to relax this restriction.)

We sometimes write  $\Gamma[c]$  to mean  $hdl(\Gamma(c))$ .

Figure 6 shows the type checking rules for statements. The judgments are of the form  $\Gamma, i, \Psi \vdash s : \Psi'$  where i is the index of the process where s appears in,  $\Psi$  the capabilities before s, and  $\Psi'$  the capabilities after s. **SEQ**, **IF**, **WHILE**, SKIP, and ASSIGN are self-explanatory. WRITE handles channel writes and **READ** handles channel reads. Here,  $confch(\tau, \Gamma)$  is defined as:

$$confch(\tau, \Gamma) \Leftrightarrow \exists c. \Gamma[c] = hdl(\tau) \land confch(c)$$

We write  $\Gamma \vdash B(c)$  if the buffer B(c) is well-typed, i.e.,  $\Gamma \vdash e : valtype(\Gamma(c))$ for each value e stored in the buffer B(c). We write  $\Gamma \vdash h$  if the history h is well-typed, i.e,  $\Gamma \vdash h(x) : \Gamma(x)$  for each  $x \in dom(h)$ . We write  $\Gamma \vdash C : \Psi$  if  $\Psi$ represents C, i.e., for each  $w(c) \in dom(C)$ ,  $\Psi(w(\Gamma[c])) = C(w(c))$  and for each  $r(c) \in dom(C), \Psi(r(\Gamma[c])) = C(r(c)).$ 

Let  $\underline{P} = (B, X, S, 1.C_1.s_1 || \dots || n.C_n.s_n)$ . An environment for  $\underline{P}$  consists of a type environment  $\Gamma$  for typing the channels, a type environment  $\Gamma_i$  for typing each process i, the starting static capability  $\Psi_i$  for each process i, and the mapping W from handles to static capabilities that represents X. We say  $\underline{P}$  is well-typed under the environment  $(\Gamma, \Gamma_1, \dots, \Gamma_n, \Psi_1, \dots, \Psi_n, W)$ , written  $(\Gamma, \Gamma_1, \dots, \Gamma_n, \Psi_1, \dots, \Psi_n, W) \vdash \underline{P}$ , if

- For each c,  $\Gamma \vdash B(c)$ .

- For each i,  $\Gamma_i \supseteq \Gamma$ ,  $\Gamma_i \vdash S(i)$ ,  $\Gamma \vdash C_i : \Psi_i$ , and  $\Gamma_i, i, \Psi_i \vdash s_i : \Psi'_i$  for some  $\Psi'_i$ .
   For each c,  $\Gamma \vdash X(c) : W(\Gamma[c])$ , i.e., W is a static representation of X.
   Let  $\Psi_{total} = \sum_{i=1}^n \Psi_i + \sum_{\rho \in dom(W)} W(\rho)$ . Then for each  $cap \in dom(\Psi_{total})$ ,  $\Psi_{total}(cap) = 1$ , i.e., there are no duplicated capabilities.
- For all output buffered channels c,  $W(\Gamma[c]) = |B(c)| \times writeSend(\Gamma(c))$ . For all input buffered channels c,  $W(\Gamma[c]) = \sum_{i=1}^{n} |B(c).i| \times readRecv(\Gamma(c),i)$ .

In the last condition, |B(c)| denotes the length of the queue B(c), and |B(c).i|denotes the length of the queue for process i (for input buffered channels). The condition ensures that there are enough capabilities in X for buffered reads. We now state the main claim of this section.

**Theorem 2.** Let Y be a set of channels and let  $confch(c) \Leftrightarrow c \in Y$ . Let M = $\{\underline{P} \mid \exists Env.Env \vdash \underline{P}\}$ . Then M is capability-respecting with respect to Y.

Theorem 2 together with Theorem 1 implies that to check if P is confluent, it suffices to find a well-typed  $\underline{P}$  such that  $P = erase(\underline{P})$ . More formally,

**Corollary 1.** Let Y be a set of channels and let  $confch(c) \Leftrightarrow c \in Y$ . P is partially-confluent and deterministic with respect to Y if there exists P and Env such that  $P = erase(\underline{P})$  and  $Env \vdash \underline{P}$ .

The problem of finding  $\underline{P}$  and  $\underline{Env}$  such that  $P = erase(\underline{P})$  and  $\underline{Env} \vdash \underline{P}$  can be formulated as linear inequality constraints satisfaction problem. The details are similar to the type inference algorithm from our previous work [11]. The constraints can be generated in time polynomial to the size of P, which can then be solved efficiently by a linear programming algorithm.

#### 3.2 Examples

Producer Consumer: Let c be an output buffered channel. The program 1.while 1 do  $!(c,1) \mid\mid 2.$ while 1 do ?(c,x) is a simple but common communication pattern of sender and receiver processes being fixed for each channel; no capabilities need to be passed between processes. The type system can infer the confluence by assigning the starting capabilities  $\theta[w(\rho) \mapsto 1]$  to process 1 and  $\theta[r(\rho) \mapsto 1]$  to process 2 where  $c: ch(\rho, int, \theta)$ .

Token Ring: Let  $c_1, c_2, c_3$  be rendezvous and d be output buffered. The program below models a token ring where processes 1, 2, and 3 take turn writing to d:

```
 \begin{array}{l} \text{1.while 1 do } (?(c_3,x);!(d,1);!(c_1,0)) \\ || \ 2.\text{while 1 do } (?(c_1,x);!(d,2);!(c_2,0)) \\ || \ 3.!(c_3,0); \text{while 1 do } (?(c_2,x);!(d,3);!(c_3,0)) \\ || \ 4.\text{while 1 do } ?(d,y) \end{array}
```

Recall that variables x and y are process local. The type system can infer the confluence by assigning d the type  $ch(\rho_d, int, \theta)$  and each  $c_i$  the type  $ch(\rho_{c_i}, int, \theta[w(\rho_d) \mapsto 1], \theta)$ , which says that a write to  $c_i$  sends w(d) to the reader. The starting capabilities are  $\theta[r(\rho_{c_3}) \mapsto 1, w(\rho_{c_1}) \mapsto 1]$  for process 1,  $\theta[r(\rho_{c_1}) \mapsto 1, w(\rho_{c_2}) \mapsto 1]$  for process 2,  $\theta[r(\rho_{c_2}) \mapsto 1, w(\rho_{c_3}) \mapsto 1, w(\rho_d) \mapsto 1]$  for process 3, and  $\theta[r(\rho_d) \mapsto 1]$  for process 4.

Barrier Synchronization: Let  $c_1$ ,  $c_2$ ,  $c_3$  be reference cells. Let  $d_1$ ,  $d_2$ ,  $d_3$ ,  $d'_1$ ,  $d'_2$ ,  $d'_3$  be input buffered channels. Consider the following program:

```
1.while 1 do (!(c_1, e_1); !(d_1, 0); BR; ?(c_1, y); ?(c_2, z); ?(c_3, w); !(d'_1, 0); BR') || 2.while 1 do (!(c_2, e_2); !(d_2, 0); BR; ?(c_1, y); ?(c_2, z); ?(c_3, w); !(d'_2, 0); BR') || 3.while 1 do (!(c_3, e_3); !(d_3, 0); BR; ?(c_1, y); ?(c_2, z); ?(c_3, w); !(d'_3, 0); BR')
```

Here,  $\mathbf{BR} = ?(d_1, x); ?(d_2, x); ?(d_3, x)$  and  $\mathbf{BR'} = ?(d'_1, x); ?(d'_2, x); ?(d'_3, x)$ . The program is an example of barrier-style synchronization. Process 1 writes to  $c_1$ , process 2 writes to  $c_2$ , process 3 writes to  $c_3$ , and then the three processes synchronize via a barrier so that none of the processes can proceed until all are done with their writes. Note that  $!(d_i, 0); \mathbf{BR}$  models the barrier for each process i. After the barrier synchronization, each process reads from all three reference cells before synchronizing themselves via another barrier, this time modeled by  $!(d'_i, 0); \mathbf{BR'}$ , before the next iteration of the loop.

The type system can infer the confluence by assigning the following types (assume  $e_1$ ,  $e_2$ , and  $e_3$  are of type int):  $c_1$ :  $ch(\rho_{c1}, int)$ ,  $c_2$ :  $ch(\rho_{c2}, int)$ ,  $c_3$ :  $ch(\rho_{c3}, int)$ , and for each  $i \in \{1, 2, 3\}$ ,

```
d_i: ch(\rho_{d_i}, int, \langle \theta[w(\rho_{c_i}) \mapsto \frac{1}{3}], \theta[w(\rho_{c_i}) \mapsto \frac{1}{3}], \theta[w(\rho_{c_i}) \mapsto \frac{1}{3}] \rangle) \\ d'_i: ch(\rho_{d'_i}, int, \langle \theta[w(\rho_{c_1}) \mapsto \frac{1}{3}], \theta[w(\rho_{c_2}) \mapsto \frac{1}{3}], \theta[w(\rho_{c_3}) \mapsto \frac{1}{3}] \rangle)
```

The initial static capability set for each process i is  $\theta[w(\rho_{c_i}) \mapsto 1, w(\rho_{d_i}) \mapsto 1, w(\rho_{d_i}) \mapsto 1]$ . Note that fractional capabilities are passed at barrier synchronization points to enable reads and writes on  $c_1$ ,  $c_2$ , and  $c_3$ .

Type inference fails if the program is changed so that  $d_1, d_2, d_3$  are also used for the second barrier (in place of  $d'_1, d'_2, d'_3$ ) because while the first write to  $d_i$  must send capability to read  $c_i$ , the second write to  $d_i$  must send to each process j the capability to access  $c_j$ , and there is no single type for  $d_i$  to express this behavior. This demonstrates the *flow-insensitivity* limitation of our type system, i.e., a channel must send and receive the same capabilities every time it is used.

However, if synchronization points are syntactically identifiable (as in this example) then the program can be easily converted such that flow-insensitivity becomes sufficient by using distinct channels at each syntactic synchronization point.<sup>5</sup> In our example, the first barrier in each process matches the other, and the second barrier in each process matches the other. Synchronizations that are not syntactically identifiable are often considered as a sign of potential bugs [1]. Note that reference cells  $c_1$  and  $c_2$  are not used for synchronization and therefore need no syntactic restriction.

#### 3.3 Extensions

We discuss extensions to our system.

Regions: Aliasing becomes an issue when channels are used as values, e.g., like in a  $\pi$  calculus program. For example, our type system does not allow two different channels c and d to be passed to the same channel because two different channels cannot be given the same handle. One way to resolve aliasing is to use regions so that each  $\rho$  represents a set of channels. Then, we may give both c and d the same type  $ch(\rho, \ldots)$  at the cost of sharing  $w(\rho)$  (and  $r(\rho)$ ) for all the channels in the region  $\rho$ .

Existential Abstraction and Linear Types: Another way to resolve aliasing is to existentially abstract capabilities as in  $\exists \rho.\tau \otimes \varPsi$ . Any type containing a capability set must be handled linearly<sup>6</sup> to prevent the duplication of capabilities. The capabilities are recovered by opening the existential package. Existential abstraction can encode linearly typed channels [10,8] (for rendezvous channels) as:  $\exists \rho.ch(\rho,\tau,\theta,\theta) \otimes \theta[w(\rho) \mapsto 1,r(\rho) \mapsto 1]$ . Note that the type encapsulates both a channel and the capability to access the channel. This encoding allows transitions to and from linearly typed channels to the capabilities world, e.g., it is possible to use once a linearly-typed channel multiple times. An analogous approach has been applied to express updatable recursive data structures in the capability calculus [12].

Dynamically Created Channels: Dynamically created channels can be handled in much the same way heap allocated objects are handled in the capability

<sup>&</sup>lt;sup>5</sup> This can be done without changing the implementation. See *named barriers* in [1].

<sup>&</sup>lt;sup>6</sup> Actually, a more relaxed sub-structural type system is preferred for handling fractional capabilities [11].

calculus [4] (we only show the rule for the case where c is rendezvous):

$$\rho \text{ is not free in the conclusion}$$

$$\Gamma \cup \{c \mapsto ch(\rho, \tau, \Psi_1, \Psi_2)\}, i, \Psi + \theta[w(\rho) \mapsto 1][r(\rho) \mapsto 1] \vdash s : \Psi'$$

$$\Gamma, i, \Psi \vdash \nu c.s : \Psi'$$

Existential abstraction allows dynamically created channels to leave their lexical scope. An alternative approach is to place the newly created channel in an existing region. In this case, we can remove the hypothesis " $\rho$  is not free in the conclusion", but we also must remove the capabilities  $\theta[w(\rho) \mapsto 1][r(\rho) \mapsto 1]$ .

Dynamically Spawned Processes: Dynamic spawning of processes can be typed as follows:

$$\frac{\varGamma, i, \varPsi_2 \vdash s : \varPsi'}{\varGamma, i, \varPsi_1 + \varPsi_2 \vdash \mathtt{spawn}(s) : \varPsi_1}$$

(For simplicity, we assume that the local store of the parent process is copied for the spawned process. Details for handling input buffered channels are omitted.) Note that the spawned process may take capabilities from the parent process.

#### 4 Related Work

We discuss previous approaches to inferring partial confluence. Kahn process networks [7] restrict communication to input buffered channels with a unique sender process to guarantee determinism. Edwards et al. [5] restricts communication to rendezvous channels with a unique sender process and a unique receiver process to model deterministic behavior of embedded systems. These models are the easy cases for our system where capabilities are not passed between processes.

Linear type systems can infer partial confluence by checking that each channel is used at most once [10,8]. Section 3.3 discusses how to express linearly typed channels in our system. König presents a type system that can be parametrized to check partial confluence in the  $\pi$ -calculus [9]. Her system corresponds to the restricted case of our system where each (rendezvous) channel is given the type of the form  $ch(\rho, \tau, \theta[w(\rho) \mapsto 1], \theta[r(\rho) \mapsto 1])$ , i.e., each channel sends its own write capability at writes and sends its own read capability at reads. Therefore, for example, while her system can check the confluence of !(c,1); ?(c,x)||?(c,x); !(c,2), it cannot check the confluence of !(c,1); !(c,2)||?(c,x); ?(c,x).

A more exhaustive approach for checking partial confluence has been proposed in which the confluence for every state of the program is individually checked by following the transitions from that state [6, 2]. These methods are designed specifically to drive state space reduction, and hence have somewhat a different aim from our work. They are shown effective for programs with a small number of states.

This work was motivated by our previous work on inferring confluence in functional languages with side effects [11] (see also [3]). These systems can only reason about synchronization at join points, and therefore cannot infer confluence of channel-communicating processes.

<sup>&</sup>lt;sup>7</sup> [8] uses asynchronous  $\pi$  calculus, and so is not entirely comparable with our work.

#### 5 Conclusions

We have presented a system for inferring partial confluence of concurrent programs communicating via a mix of different kinds of communication channels. We casted our system as a capability calculus where fractional capabilities can be passed at channel communications, and presented a type system for statically inferring partial confluence by finding an appropriate capability passing strategy in the calculus.

#### A Proofs

**Lemma 1.** If P is partially confluent with respect to Y then P is deterministic with respect to Y.

*Proof.* Suppose P is partially confluent with respect to Y. Let i be a process index. For contradiction, suppose that there exist reductions  $P \to^* (B_1, S_1, p_1)$  and  $P \to^* (B_2, S_2, p_2)$  both communicating only over channels in Y such that neither  $S_1(i)$  nor  $S_2(i)$  is a prefix of the other. But since P is partially confluent, there exists Q such that  $(B_1, S_1, p_1) \to^* Q$  and  $(B_2, S_2, p_2) \to^* Q$ . But by inspection of the reduction rules, such a Q cannot exist.

**Lemma 2 (Diamond Property).** Let P be a state. Suppose there exists M such that M is capability-respecting with respect to Y and there exists  $\underline{P} \in M$  such that  $\operatorname{erase}(\underline{P}) = P$ . Suppose  $P \to P_1$  communicating only over channels in Y and  $P \to P_2$ . Then either  $P_1 = P_2$  or there exists Q such that  $P_2 \to Q$  communicating only over channels in Y and  $P_1 \to Q$ .

*Proof.* We prove the result by case analysis on  $P \to P_1$ . Note that because  $\underline{P} \in M$ , there exist  $P_1$  and  $P_2$  such that

- $erase(\underline{P_1}) = P_1$  and  $erase(\underline{P_2}) = P_2$ , and
- $\underline{P} \xrightarrow{\ell_1} \underline{P_1}$  and  $\underline{P} \xrightarrow{\ell_2} \underline{P_2}$  and neither  $\ell_1$  nor  $\ell_2$  is false.

The case where  $P \to P_1$  is a sequential reduction (i.e., **IF1**, **IF2**, **WHILE1**, **WHILE2**, or **ASSIGN**) is trivial. Suppose  $P \to P_1$  is:

$$\begin{array}{c} (S(i), e_1) \Downarrow c & (S(i), e_2) \Downarrow e_2' & (S(j), e_3) \Downarrow c \\ \hline \neg \textit{buffered}(c) & S' = S[j \mapsto S(j) :: (x, e_2')] \\ \hline (B, S, i.!(e_1, e_2); s_1 || j.?(e_3, x); s_2 || p) \rightarrow (B, S', i.s_1 || j.s_2 || p) \end{array}$$

where  $P=(B,S,i.!(e_1,e_2);s_1||j.?(e_3,x);s_2||p)$  and  $P_1=(B,S',i.s_1||j.s_2||p)$ . By assumption,  $c\in Y$ . If  $P\to P_2$  does not communicate over c, then the result follows trivially. So suppose  $P\to P_2$  communicates over c. Let i' and j' be the process indexes such that  $\underline{P}\xrightarrow{\ell_2}\underline{P_2}$  is between the writer process i' and the reader process j'. But because  $\ell_1=\ell_2=true,\,\underline{P}$  being well-formed implies that i=i' and j=j'. Therefore,  $P_1=P_2$ .

Suppose  $P \to P_1$  is:

$$\frac{(S(i), e_1) \Downarrow c \quad (S(i), e_2) \Downarrow e'_2 \quad \textit{buffered}(c) \quad B' = B.\textit{write}(c, e'_2)}{(B, S, i.!(e_1, e_2); s||p) \rightarrow (B', S, i.s||p)}$$

where  $P=(B,S,i.!(e_1,e_2);s||p)$  and  $P_1=(B',S,i.s||p)$ . Suppose c is output buffered or input buffered. By the assumption,  $c\in Y$ . If  $P\to P_2$  does not communicate over c, then the result follows trivially. Also, if  $P\to P_2$  is a read from c, then because buffers are FIFO, the result follows trivially. So suppose  $P\to P_2$  writes c. Let i' be the process indexes such that  $P\to P_2$  is a write by process i'. But because  $\ell_1=\ell_2=true, P$  being well-formed implies that i=i'. Therefore,  $P_1=P_2$ .

The case where  $P \to P_1$  reads an output buffered channel is similar. The case where  $P \to P_1$  reads an input buffered channel follows trivially from the fact that input buffers are process local.

Suppose  $P \to P_1$  is:

$$\frac{(S(i), e_1) \Downarrow c \quad (S(i), e_2) \Downarrow e'_2 \quad \textit{buffered}(c) \quad B' = B.\textit{write}(c, e'_2)}{(B, S, i.!(e_1, e_2); s||p) \rightarrow (B', S, i.s||p)}$$

where  $P = (B, S, i.!(e_1, e_2); s||p)$  and  $P_1 = (B', S, i.s||p)$ . Suppose c is a reference cell. By assumption,  $c \in Y$ . If  $P \to P_2$  does not communicate over c, then the result follows trivially. So suppose  $P \to P_2$  communicates over c (read or write). Let i' be the process indexes such that  $\underline{P} \xrightarrow{\ell_2} \underline{P_2}$  is a write or a read by process i'. But because  $\ell_1 = \ell_2 = true$ ,  $\underline{P}$  being well-formed implies that i = i' (so  $P \to P_2$  is in fact a write). Therefore,  $P_1 = P_2$ .

Suppose  $P \to P_1$  is:

$$(S(i), e) \Downarrow c \quad buffered(c) \quad (B', e') = B.read(c, i) \quad S' = S[i \mapsto S(i) :: (x, e')]$$
$$(B, S, i.?(e, x); s||p) \rightarrow (B', S', i.s||p)$$

where P=(B,S,i.?(e,x);s||p) and  $P_1=(B',S',i.s||p)$ . Suppose c is a reference cell. By assumption,  $c \in Y$ . If  $P \to P_2$  does not communicate over c, then the result follows trivially. Also, if  $P \to P_2$  is a read from c then because reading a reference cell is non-destructive, the result follows trivially. So suppose  $P \to P_2$  writes to c. But because  $\ell_1 = \ell_2 = true$ ,  $\underline{P}$  being well-formed implies that  $P \to P_2$  is, in fact, not a write to c.

**Theorem 1.** Let P be a state. Suppose there exists M such that M is capability-respecting with respect to Y and there exists  $\underline{P} \in M$  such that  $erase(\underline{P}) = P$ . Then P is partially confluent with respect to Y.

*Proof.* Note that for any  $\underline{P} \in M$ , if  $erase(\underline{P}) \to^* Q$  then there exists  $\underline{Q} \in M$  such that  $erase(\underline{Q}) = Q$ . Therefore, the proof is a standard inductive application of the diamond property (Lemma 2).

**Lemma 3.** If  $\Gamma, i, \Psi_1 \vdash s : \Psi_2$  and  $\Psi_1' \geq \Psi_1$ , then  $\Gamma, i, \Psi_1' \vdash s : \Psi_2'$  for some  $\Psi_2' \geq \Psi_2$ 

*Proof.* By structural induction on the type derivation.

**Lemma 4.** If  $\Gamma \vdash h$ ,  $\Gamma \vdash e : \tau$ , and  $(h, e) \Downarrow e'$ , then  $\Gamma \vdash e' : \tau$ .

*Proof.* By structural induction on the type derivation.

**Lemma 5.**  $\Gamma$ , i,  $\Psi \vdash (s_1; s_2); s_3 : \Psi'$  iff  $\Gamma$ , i,  $\Psi \vdash s_1; (s_2; s_3) : \Psi'$ .

*Proof.* By inspection of the type checking rules.

**Theorem 2.** Let Y be a set of channels and let  $confch(c) \Leftrightarrow c \in Y$ . Let  $M = \{\underline{P} \mid \exists Env.Env \vdash \underline{P}\}$ . Then M is capability-respecting with respect to Y.

*Proof.* It suffices to show that if  $Env \vdash \underline{P}$ , then

(1)  $\underline{P}$  is well-formed, and

(2) for any state Q such that  $erase(\underline{P}) \to Q$ , there exists  $\underline{Q}$  and Env' such that  $Env' \vdash Q$ , erase(Q) = Q,  $\underline{P} \stackrel{\ell}{\to} Q$ , and if  $\ell$  is not empty then  $\ell = true$ .

Suppose  $Env \vdash \underline{P}$ . From the second, the third, and the fourth conditions of  $Env \vdash \underline{P}$ , it follows that  $\underline{P}$  is well-formed. Thus it suffices to show that (2) holds. Let Q be a state such that  $erase(\underline{P}) \to Q$ . Let  $P = erase(\underline{P})$ . Let  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi_1, \ldots, \Psi_n, W) = Env$ . We show that there exist  $\underline{Q}, \Psi'_1, \ldots, \Psi'_n$ , and W' such that  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi'_1, \ldots, \Psi'_n, W') \vdash \underline{Q}, \underline{P} \xrightarrow{\ell} \underline{Q}$ , and if  $\ell$  is not empty then  $\ell = true$ . (So in fact, Env and Env' share the same  $\Gamma, \Gamma_1, \ldots, \Gamma_n$ , indicating the flow-insensitivity of our system.) We prove by case analysis on  $P \to Q$ .

Throughout this proof, we implicitly use Lemma 5 to convert a type derivation for any sequential composition  $s_1; s_2; \ldots; s_n$  to a derivation for  $s_1; (s_2; \ldots; s_n)$ . Also, note that typability is invariant under process re-ordering and sequential skip compositions (i.e., s = s; skip = skip; s).

Suppose  $P \to Q$  is

$$\frac{(S(i),e) \Downarrow n \qquad \qquad n \neq 0}{(B,S,i.(\texttt{if }e\texttt{ then }s_1\texttt{ else }s_2);s||p) \rightarrow (B,i.s_1;s||p)}$$

where  $P = (B, S, i.(\text{if } e \text{ then } s_1 \text{ else } s_2); s||p)$  and  $Q = (B, i.s_1; s||p)$ . Let  $(X, B, S, i.C_i.((\text{if } e \text{ then } s_1 \text{ else } s_2); s||p') = \underline{P}$ . Let  $\underline{Q} = (X, B, S, i.C_i.s_1; s||p')$ . Note that  $erase(\underline{Q}) = Q$  and  $\underline{P} \to \underline{Q}$ . By assumption,

$$\frac{ \Gamma_i \vdash e : int \quad \Gamma_i, i, \Psi_i \vdash s_1 : \Psi_{i1} \quad \Gamma_i, i, \Psi_i \vdash s_2 : \Psi_{i2} \quad \Psi_{i1} \geq \Psi_{i3} \quad \Psi_{i2} \geq \Psi_{i3} }{ \Gamma_i, i, \Psi_i \vdash \text{if } e \text{ then } s_1 \text{ else } s_2 : \Psi_{i3} }$$

$$\frac{\Gamma_i, i, \Psi_i \vdash \text{if } e \text{ then } s_1 \text{ else } s_2 : \Psi_{i3} \qquad \Gamma_i, i, \Psi_{i3} \vdash s : \Psi_{i4}}{\Gamma_i, i, \Psi_i \vdash (\text{if } e \text{ then } s_1 \text{ else } s_2); s : \Psi_{i4}}$$

Therefore, by Lemma 3,  $\Gamma_i, i, \Psi_{i1} \vdash s : \Psi_{i5}$  for some  $\Psi_{i5}$ . And so,  $\Gamma_i, i, \Psi_i \vdash s_1; s : \Psi_{i5}$ . Let  $\Psi'_j = \Psi_j$  for each  $j \in \{1 \dots n\}$  and W' = W. Then it follows that  $(\Gamma, \Gamma_1, \dots, \Gamma_n, \Psi'_1, \dots, \Psi'_n, W') \vdash \underline{Q}$ .

The cases where  $P \to Q$  is  $\overline{\mathbf{IF2}}$ , WHILE1, or WHILE2 can be proven in a similar manner.

Suppose  $P \to Q$  is

$$\frac{(S(i),e) \Downarrow e' \quad S' = S[i \mapsto S(i) :: (x,e')]}{(B,S,i.x := e;s||p) \to (B,S',i.s||p)}$$

where P = (B, S, i.x := e; s||p) and Q = (B, S', i.s||p). Let  $(X, B, S, i.C_i.x := e; s||p') = \underline{P}$ . Let  $\underline{Q} = (X, B, S', i.C_i.s||p')$ . Note that  $erase(\underline{Q}) = Q$  and  $\underline{P} \to \underline{Q}$ . By assumption,

$$\frac{\Gamma_i \vdash e : \Gamma_i(x)}{\Gamma_i, i, \Psi_i \vdash x := e : \Psi_i}$$

$$\frac{\Gamma_i, i, \Psi_i \vdash x := e : \Psi_i \qquad \Gamma_i, i, \Psi_i \vdash s : \Psi_{i1}}{\Gamma_i, i, \Psi_i \vdash x := e; s : \Psi_{i1}}$$

From  $\Gamma_i \vdash S(i)$ ,  $\Gamma_i \vdash e : \Gamma_i(x)$ , and Lemma 4, it follows that  $\Gamma_i \vdash S'(i)$ . Let  $\Psi'_j = \Psi_j$  for each  $j \in \{1, \ldots, n\}$  and W' = W. Then it follows that  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi'_1, \ldots, \Psi'_n, W') \vdash \underline{Q}$ .

Suppose  $P \to Q$  is

$$(S(i), e_1) \Downarrow c \qquad (S(i), e_2) \Downarrow e'_2 \qquad (S(j), e_3) \Downarrow c \neg buffered(c) \qquad S' = S[j \mapsto S(j) :: (x, e'_2)] \hline (B, S, i.!(e_1, e_2); s_1||j.?(e_3, x); s_2||p) \rightarrow (B, S', i.s_1||j.s_2||p)$$

where  $P = (B, S, i.!(e_1, e_2); s_1||j.?(e_3, x); s_2||p)$  and  $Q = (B, S', i.s_1||j.s_2||p)$ . Let  $(X, B, S, i.C_i.!(e_1, e_2); s_1||j.C_j.?(e_3, x); s_2||p')) = \underline{P}$ . By assumption,

$$\frac{\Gamma_i \vdash e_1 : \tau \qquad \Gamma_i \vdash e_2 : valtype(\tau) \qquad confch(\tau, \Gamma_i) \Rightarrow hasWcap(\Psi_i, \tau)}{\Gamma_i, i, \Psi_i \vdash !(e_1, e_2) : \Psi_{i1}}$$

$$\frac{\Gamma_i, i, \Psi_i \vdash !(e_1, e_2) : \Psi_{i1} \qquad \Gamma_i, i, \Psi_{i1} \vdash s : \Psi_{i2}}{\Gamma_i, i, \Psi_i \vdash !(e_1, e_2); s : \Psi_{i2}}$$

$$\frac{\Gamma_j \vdash e_3 : \tau' \qquad \Gamma_j(x) = valtype(\tau') \qquad confch(\tau', \Gamma_j) \Rightarrow hasRcap(\Psi_j, \tau')}{\Gamma_j, j, \Psi_j \vdash ?(e_3, x) : \Psi_{j1}}$$

$$\frac{\Gamma_j, j, \Psi_j \vdash ?(e_3, x) : \Psi_{j1} \qquad \Gamma_j, j, \Psi_{j1} \vdash s : \Psi_{j2}}{\Gamma_j, j, \Psi_j \vdash ?(e_3, x); s : \Psi_{j2}}$$

where  $\Psi_{i1} = \Psi_i - writeSend(\tau) + writeRecv(\tau)$  and  $\Psi_{j1} = \Psi_j - readSend(\tau') + readRecv(\tau', j)$ . Lemma 4 implies that  $\Gamma(c) = \tau = \tau'$ . Let C and C' be capability sets such that  $\Gamma \vdash C$ :  $writeSend(\tau)$  and  $\Gamma \vdash C'$ :  $readSend(\tau)$ . Let  $Q = (B, S', i.(C_i - C + C').s_1||j.(C_j + C - C').s_2||p)$ . Note that erase(Q) = Q. Let  $\Psi'_i = \Psi_{i1}, \ \Psi'_j = \Psi_{j1}$ , and  $\Psi'_k = \Psi_k$  for each  $k \in \{1, \ldots, n\} \setminus \{i, j\}$ . Because c must be rendezvous,  $\Psi'_i + \Psi'_j = \Psi_i + \Psi_j$ . Also,  $\Gamma \vdash (C_i - C + C') : \Psi'_i$  and  $\Gamma \vdash (C_j + C - C') : \Psi'_j$ . Therefore it follows that  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi'_1, \ldots, \Psi'_n, W') \vdash Q$ .

Suppose confch(c) holds. Then  $confch(\tau, \Gamma_i)$  and  $confch(\tau', \Gamma_j)$ , and so  $has Wcap(\Psi_i, \tau)$  and  $has Rcap(\Psi_j, \tau')$ . Therefore,  $has Wcap(C_i, c)$  and  $has Rcap(C_j, c)$ . Thus it follows that  $\underline{P} \xrightarrow{true} \underline{Q}$ . On the other hand, if  $\neg confch(c)$ , then  $\underline{P} \xrightarrow{true} \underline{Q}$  trivially.

Suppose  $P \to Q$  is

$$\frac{(S(i), e_1) \Downarrow c \quad (S(i), e_2) \Downarrow e'_2 \quad \textit{buffered}(c) \quad B' = B.\textit{write}(c, e'_2)}{(B, S, i.!(e_1, e_2); s||p) \rightarrow (B', S, i.s||p)}$$

where  $P = (B, S, i.!(e_1, e_2); s||p)$  and Q = (B', S, i.s||p). Let  $(X, B, S, i.C.!(e_1, e_2); s||p) = \underline{P}$ . By assumption,

$$\frac{\Gamma_i \vdash e_1 : \tau \qquad \Gamma_i \vdash e_2 : valtype(\tau) \qquad confch(\tau, \Gamma_i) \Rightarrow hasWcap(\Psi_i, \tau)}{\Gamma_i, i, \Psi_i \vdash ! (e_1, e_2) : \Psi_{i1}}$$

$$\frac{\Gamma_i, i, \Psi_i \vdash !(e_1, e_2) : \Psi_{i1} \qquad \Gamma_i, i, \Psi_{i1} \vdash s : \Psi_{i2}}{\Gamma_i, i, \Psi_i \vdash !(e_1, e_2); s : \Psi_{i2}}$$

where  $\Psi_{i1} = \Psi_i - writeSend(\tau) + writeRecv(\tau)$ , and  $\Gamma_i$  and  $\Psi_i$  are from the definition of  $\Gamma \vdash \underline{P}$ . Let C' be a capability set such that  $\Gamma \vdash C'$ :  $writeSend(\tau)$ . Let  $\underline{Q} = (X[c \mapsto X(c) + C'], B', S, i.(C - C').s||p)$ . Note that  $erase(\underline{Q}) = Q$ . Let  $\overline{W'} = W[\Gamma[c] \mapsto W(\Gamma[c]) + writeSend(\tau)]$ . Note that  $\forall d.\Gamma \vdash X[c \mapsto X(c) + C'](d)$ :  $W'(\Gamma[d])$ . Lemma 4 implies that  $\Gamma(c) = \tau$ . Let  $\Psi'_i = \Psi_{i1}$  and  $\Psi'_j = \Psi_j$  for each  $j \in \{1, \ldots, n\} \setminus \{i\}$ . Because c is not rendezvous,  $writeRecv(\tau) = 0$ . Therefore,  $\Psi_i + \sum_{\rho \in dom(W)} W(\rho) = \Psi'_i + \sum_{\rho \in dom(W')} W'(\rho)$ . Also,  $\Gamma \vdash (C_i - C)$ :  $\Psi'_i$ . Also, for each d output buffered,  $W'(\Gamma[d]) = |B'(d)| \times writeSend(\Gamma(d))$ , and for each d input buffered,  $W'(\Gamma[d]) = \sum_{j=1}^n |B'(d).j| \times readRecv(\Gamma(d),j)$ . Therefore it follows that  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi'_1, \ldots, \Psi'_n, W') \vdash Q$ .

Suppose confch(c) holds. Then  $confch(\tau, \Gamma_i)$ , and so  $has Wcap(\Psi_i, \tau)$ . Therefore, has Wcap(C, c). Thus it follows that  $\underline{P} \stackrel{true}{\to} \underline{Q}$ . On the other hand, if  $\neg confch(c)$ , then  $\underline{P} \stackrel{true}{\to} \underline{Q}$  trivially.

Suppose  $P \to Q$  is

$$(S(i), e) \Downarrow c \quad buffered(c) \quad (B', e') = B.read(c, i) \quad S' = S[i \mapsto S(i) :: (x, e')]$$
$$(B, S, i.?(e, x); s||p) \rightarrow (B', S', i.s||p)$$

where P = (B, S, i.?(e, x); s||p) and Q = (B', S', i.s||p). Let  $(X, B, S, i.C.?(e, x); s||p) = \underline{P}$ . By assumption,

$$\frac{\Gamma_i \vdash e : \tau \qquad \Gamma_i(x) = valtype(\tau) \qquad confch(\tau, \Gamma_i) \Rightarrow hasRcap(\Psi_i, \tau)}{\Gamma_i, i, \Psi_i \vdash ?(e, x) : \Psi_{i1}}$$

$$\frac{\Gamma_i, i, \Psi_i \vdash ?(e, x) : \Psi_{i1} \quad \Gamma_i, i, \Psi_{i1} \vdash s : \Psi_{i2}}{\Gamma_i, i, \Psi_i \vdash ?(e, x); s : \Psi_{i2}}$$

where  $\Psi_{i1} = \Psi_i - readSend(\tau) + readRecv(\tau,i)$ . Let C' be a capability set such that  $\Gamma \vdash C' : readRecv(\tau,i)$ . Let  $Q = (X[c \mapsto X(c) - C'], B', S', i.(C + C').s||p)$ . Note that erase(Q) = Q. Let  $W' = W[\Gamma[c] \mapsto W(\Gamma[c]) - readRecv(\tau,i)]$ . Note that  $\forall d.\Gamma \vdash X[c \mapsto X(c) - C'](d) : W'(\Gamma[d])$ . Lemma 4 implies that  $\Gamma(c) = \tau$ . Let  $\Psi'_i = \Psi_{i1}$  and  $\Psi'_j = \Psi_j$  for each  $j \in \{1, \ldots, n\} \setminus \{i\}$ . Because c is not rendezvous,  $readSend(\tau) = 0$ . Therefore,  $\Psi_i + \sum_{\rho \in dom(W)} W(\rho) = \Psi'_i + \sum_{\rho \in dom(W')} W'(\rho)$ . Also, for each d output buffered,  $W'(\Gamma[d]) = |B'(d)| \times writeSend(\Gamma(d))$ , and for each d input buffered,  $W'(\Gamma[d]) = \sum_{j=1}^n |B'(d).j| \times readRecv(\Gamma(d),j)$ . Therefore it follows that  $(\Gamma, \Gamma_1, \ldots, \Gamma_n, \Psi'_1, \ldots, \Psi'_n, W') \vdash Q$ . Suppose confch(c) holds. Then  $confch(\tau, \Gamma_i)$ , and so  $hasRcap(\Psi_i, \tau)$ . Therefore

Suppose confch(c) holds. Then  $confch(\tau, \Gamma_i)$ , and so  $hasRcap(\Psi_i, \tau)$ . Therefore, hasRcap(C, c). Thus it follows that  $\underline{P} \stackrel{true}{\to} \underline{Q}$ . On the other hand, if  $\neg confch(c)$ , then  $\underline{P} \stackrel{true}{\to} \underline{Q}$  trivially.
