June 14, 1992

Abstract

Relations between the field of values of a matrix $A$ and those of its Schur complements are established. This work began with an attempt to get rid of pivoting from Gauss elimination under certain circumstances when the field of values $\mathcal{F}(A)$ does not contain the origin. The upper bound proved in this paper must be improved before it is of more practical use. However, the proof of the upper bound does provide an intuition on how a tight upper bound looks like.

1 Kahan’s Theorems

Let $A$ be an $n \times n$ complex matrix. The field of values of $A$ is defined to be the set

$$\mathcal{F}(A) \overset{\text{def}}{=} \{ x^*Ax/x^*x : 0 \neq x \text{ is a } n\text{-dimensional vector} \}. $$

(Here the superscript * means taking conjugate transpose.) Toeplitz–Hausdorff Theorem says that $\mathcal{F}(A)$ is convex. Now partition $A$ as

$$A = \begin{pmatrix} H & R \\ L & V \end{pmatrix},$$

where $H$ is of $m \times m$ ($1 \leq m \leq n - 1$). If $H$ is invertible,

$$X \overset{\text{def}}{=} V - LH^{-1}R$$

is called the Schur complement of $H$ in $A$. The following theorem establishes a relation between $\mathcal{F}(A)$ and $\mathcal{F}(X)$.

**Theorem 1** Let $\alpha \in \mathcal{F}(X)$. Then there exist a $\beta \in \mathcal{F}(A)$ and a positive number $\gamma$ with $1 \leq \gamma \leq 1 + \| LH^{-1} \|_2^2$, where $\| \cdot \|_2$ is the spectral norm of a matrix, such that $\alpha = \gamma \beta$.

**Proof:** Note

$$\begin{pmatrix} I & 0 \\ -LH^{-1} & I \end{pmatrix} \begin{pmatrix} H & R \\ L & V \end{pmatrix} \begin{pmatrix} I & -H^{-*}L^* \\ 0 & I \end{pmatrix} = \begin{pmatrix} H & R \\ 0 & V - LH^{-1}R \end{pmatrix} \begin{pmatrix} I & -H^{-*}L^* \\ 0 & I \end{pmatrix} = \begin{pmatrix} H & R - HH^{-*}L^* \\ 0 & X \end{pmatrix} \overset{\text{def}}{=} C. \tag{3}$$

Denote

$$M = \begin{pmatrix} I & 0 \\ -LH^{-1} & I \end{pmatrix}. $$
Then $C = MAM^*$ by (3). For any $n$–dimensional vector $y$, letting $x = M^*y$, we get then

$$\frac{y^*Cy}{y^*y} = \frac{x^*Ax}{x^*x}.$$

(4)

Consider now those vector $y$ having form

$$y = \begin{pmatrix} 0 \\ z \end{pmatrix},$$

(5)

where $z$ is of $n - m$–dimension. Then

$$y^*Cy = z^*Xz, \quad x = \begin{pmatrix} -H^{-1}L^*z \\ z \end{pmatrix}.$$  

(6)

Hence $\|x\|_2^2 = \|z\|_2^2 + \|LH^{-1}z\|_2^2 \leq (1 + \|LH^{-1}\|_2^2)\|z\|_2^2$. Since $\|y\|_2 = \|z\|_2$,

$$1 \leq \frac{x^*x}{y^*y} \leq 1 + \|LH^{-1}\|_2^2.$$  

By the definition of the field of values of a matrix, the conclusion of the theorem follows from (4).

It has been proved that the field of values of any $2 \times 2$ matrix is an ellipse. More precisely, let $T = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, and let $U$ be the $2 \times 2$ unitary matrix such that

$$U^*TU = \begin{pmatrix} \lambda_1 & \delta \\ 0 & \lambda_2 \end{pmatrix},$$

where $\lambda_1$ and $\lambda_2$ are the eigenvalues of $T$, $\delta$ is nonnegative and equals to $(|a|^2 + |b|^2 + |c|^2 + |d|^2 - |\lambda_1|^2 - |\lambda_2|^2)^{1/2}$. The field of values $\mathcal{F}(T)$ is the ellipse with two foci $\lambda_1$ and $\lambda_2$ and semi-minor $|\delta|/2$. (It is a straight line segment joining $\lambda_1$ and $\lambda_2$ if $\delta = 0$, i.e., $T$ is a normal matrix.) On the other hand, an ellipse on the complex plane corresponding to infinitely many $2 \times 2$ matrix unless the ellipse degenerates to a point.

There is only one Schur complement in a $2 \times 2$ matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ which is $d - \frac{bc}{a}$ provided $a \neq 0$. 

For any vector $x \neq 0$, partition it conformly to (1) as $x = (x_1^T, x_2^T)^T$. (Here the superscript $^T$ means taking transpose.) Note
\[
x^*Ax = x_1^*Hx_1 + x_1^*Rx_2 + x_2^*Lx_1 + x_2^*Vx_2.
\]
We claim that there are complex numbers $a, b, c, d$ and $\xi_j$ with $\|x_j\|_2 = |\xi_j|$ such that
\[
\begin{align*}
x_1^*Hx_1 &= a|\xi_1|^2, \\
x_1^*Rx_2 &= b\xi_1\xi_2, \\
x_2^*Lx_1 &= c\xi_1\xi_2, \\
x_2^*Vx_2 &= d|\xi_2|^2.
\end{align*}
\]
As a matter of fact, we could simply take $\xi_j = \|x_j\|_2$, then solve for $a, b, c, d$ in the following way:

- **The case** $x_1 \neq 0$ and $x_2 \neq 0$: Then $\xi_1 \neq 0$ and $\xi_2 \neq 0$. Hence
  \[
a = \frac{x_1^*Hx_1}{|\xi_1|^2}, \quad b = \frac{x_1^*Rx_2}{\xi_1\xi_2}, \quad c = \frac{x_2^*Lx_1}{\xi_1\xi_2}, \quad d = \frac{x_2^*Vx_2}{|\xi_2|^2}.
\]

- **The case** $x_1 = 0$ and $x_2 \neq 0$: Then $\xi_1 = 0$ and $\xi_2 \neq 0$. Set $a = b = c = 0$ and $d = x_2^*Vx_2/|\xi_2|^2$.

- **The case** $x_1 \neq 0$ and $x_2 = 0$: Then $\xi_1 \neq 0$ and $\xi_2 = 0$. Set $a = x_1^*Hx_1/|\xi_1|^2$ while set $b = c = d = 0$.

**Claim:** The field of values of the $2 \times 2$ matrix $T = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, which is an ellipse, is contained in $\mathcal{F}(A)$.

**Proof:** The case when $x_1 = 0$ or $x_2 = 0$ is trivial. In the following we consider the case when none of the two is zero. For any $g = (\zeta_1, \zeta_2)^T$, let $\rho_j = \zeta_j/\xi_j$. It is easy to verify
\[
\frac{g^*Tg}{g^*g} = \frac{\begin{pmatrix} \rho_1x_1 \\ \rho_2x_2 \end{pmatrix}^*A \begin{pmatrix} \rho_1x_1 \\ \rho_2x_2 \end{pmatrix}}{\|\rho_1\|^2\|x_1\|_2^2 + \|\rho_2\|^2\|x_2\|_2^2} \in \mathcal{F}(A).
\]
Recall the equations (4), (5) and (6). Consider now $x_2 = z$ (with $z^*z = 1$) and $x_1 = -H^*L^*z$. For the present case $x_1^*Hx_1 + x_2^*Lx_1 = 0$. Thus $a|\xi_1|^2 + c\xi_1\xi_2 = 0$. Assume, for the moment, $\xi_1 \neq 0$. Then $\xi_1 = -\frac{c}{a}\xi_2$, provided $a \neq 0$. By (4), we see ($z^*z = y^*y = 1 \Rightarrow |\xi_2| = 1$)

$$z^*Xz = x^*Ax = d - \frac{bc}{a},$$

if $a \neq 0$, which is guaranteed if we assume $0 \notin \mathcal{F}(H)$. If, however, $\xi = 0$, then by the construction of the $2 \times 2$ matrix $T$, $x_1 = 0$ which implies $L^*z = 0$. Thus $z^*Xz = x^*Ax = x_2^*Vx_2 = d$, which can be regarded as the Schur complement in a matrix like $\begin{pmatrix} d & 0 \\ 0 & d \end{pmatrix}$. Thus we have proved

**Theorem 2** If $0 \notin \mathcal{F}(H)$, then any point in $\mathcal{F}(X)$ is a Schur complement in a $2 \times 2$ matrix whose field of values is contained completely in $\mathcal{F}(A)$.

## 2 The Region of Schur Complements of All 2 × 2 Matrices with a Fixed Field of Values

**Lemma 1** Let $T$ be a $2 \times 2$ matrix, and $D$ a $2 \times 2$ diagonal unitary matrix. Then $T$ and $DTD^*$ have the same Schur complement.

Given an ellipse $\mathcal{E}(\lambda_1, \lambda_2, m)$ with the two foci $\lambda_1$ and $\lambda_2$ and semi-minor $m$, all possible $2 \times 2$ matrices whose fields of values are $\mathcal{E}(\lambda_1, \lambda_2, m)$ are

$$U \begin{pmatrix} \lambda_1 & \delta \\ 0 & \lambda_2 \end{pmatrix} U^*,$$

where $U$ runs over all $2 \times 2$ unitary matrices, and $\delta = 2m$. Since any $2 \times 2$ unitary matrix $U$ can be decomposed as

$$U = \begin{pmatrix} d_1 & 0 \\ 0 & d_2 \end{pmatrix} \begin{pmatrix} e & -s \\ \overline{s} & \overline{e} \end{pmatrix},$$
where \(|d_1| = |d_2| = 1\) and \(|c|^2 + |s|^2 = 1\). By Lemma 1, to study Schur complements of all possible \(2 \times 2\) matrices with the field of values \(\mathcal{E}(\lambda_1, \lambda_2, m)\), it suffices for us to consider these matrices

\[
\begin{pmatrix}
    c & -s \\
    \bar{s} & \bar{c}
\end{pmatrix}
\begin{pmatrix}
    \lambda_1 & \delta \\
    0 & \lambda_2
\end{pmatrix}
\begin{pmatrix}
    \bar{c} & s \\
    -\bar{s} & c
\end{pmatrix} = \begin{pmatrix}
    |c|^2\lambda_1 + |s|^2\lambda_2 - c\bar{s}\delta & cs(\lambda_1 - \lambda_2) + c^2\delta \\
    c\bar{s}(\lambda_1 - \lambda_2) - \bar{s}^2\delta & |s|^2\lambda_1 + |c|^2\lambda_2 + c\bar{s}\delta
\end{pmatrix},
\]

whose only Schur complement is

\[
\frac{\lambda_1 \lambda_2}{|c|^2\lambda_1 + |s|^2\lambda_2 - c\bar{s}\delta}.
\] (8)

**Lemma 2**

\[
\mathcal{E}(\lambda_1, \lambda_2, m) = \{|c|^2\lambda_1 + |s|^2\lambda_2 - c\bar{s}\delta : |c|^2 + |s|^2 = 1\}
\]

\[
= \{|s|^2\lambda_1 + |c|^2\lambda_2 - c\bar{s}\delta : |c|^2 + |s|^2 = 1\}.
\]

From now on, for convenience, we will not distinguish a complex number and the unique point it represents on the complex plane. For a set \(D\) consisting of complex numbers, the notation \(|D|\) is defined as

\[
|D| = \max\{|z| : z \in D\}.
\]

We assume \(\mathcal{E}(\lambda_1, \lambda_2, m)\) does not contain the origin, i.e.,

\[
\mathcal{E}(\lambda_1, \lambda_2, m) \not\ni 0.
\] (9)

Our interest is the region \(\mathcal{R}(\lambda_1, \lambda_2, m)\) of all possible values of \( (8) \) for all possible \(c\) and \(s\) subject to \(|c|^2 + |s|^2 = 1\). By Lemma 2, we see

\[
\mathcal{R}(\lambda_1, \lambda_2, m) = \{\lambda_1 \lambda_2/z : z \in \mathcal{E}(\lambda_1, \lambda_2, m)\}.
\] (10)

Now, we try to find an upper bound for \(|\mathcal{R}(\lambda_1, \lambda_2, m)|\). Let \(t_1\) and \(t_2\) be two tangent lines of \(\mathcal{E}(\lambda_1, \lambda_2, m)\) coming from the origin. The two lines divide the complex plane into two sectors. \(\mathcal{E}(\lambda_1, \lambda_2, m)\) lies in the smaller
Figure 1: An Ellipse

one. Let $\theta$ be the angle of the smaller sector. (Note $0 \leq \theta < \pi$! $\theta = 0$
if $\frac{\lambda_2}{\lambda_1}$ is real.) Draw two lines $\ell_1$ and $\ell_2$ connecting the origin and $\lambda_1$, the
origin and $\lambda_2$, respectively. Let $\psi$ be the smaller angle between $\ell_1$ and
$\ell_2$ ($0 < \psi \leq \theta$ and $\psi = \theta$ if $m = 0$). Let $\ell$ be the line joining $\lambda_1$ and $\lambda_2$.
Consider now a point in $R(\lambda_1, \lambda_2, m)$, which is of form (8). Its absolute value
reaches its maximum when the absolute value of its denominator reaches its
minimum, which means, by Lemma 2, the maximum occurs at the closest
point of $E(\lambda_1, \lambda_2, m)$ to the origin. Let $c_0$ and $s_0$ with $|c_0|^2 + |s_0|^2 = 1$ be
the numbers for which

$$\left| |c_0|^2 \lambda_1 + |s_0|^2 \lambda_2 - c_0 s_0 \delta \right| = \min_{|c|^2 + |s|^2 = 1} \left\{ \left| |c|^2 \lambda_1 + |s|^2 \lambda_2 - c s \delta \right| \right\}.$$ 

Then it is easy to see $c_0 s_0 \delta = 2|c_0 s_0| m$. In another word, $c_0 s_0 \delta$ has to be
real and positive. Draw a circle with center $|c_0|^2 \lambda_1 + |s_0|^2 \lambda_2$ and radius
$2|c_0 s_0| m$. The following facts are easy to establish:

- The circle lies inside the ellipse $E(\lambda_1, \lambda_2, m)$ completely;
• The center of the circle lies on the line $\ell$ joining the two foci $\lambda_1$ and $\lambda_2$;

• The circle is tangent to the boundary of the ellipse at two points one of which is closer to the origin. Let $P$ denote the closer point:

1. The point $P$ lies on the line segment joining the origin and $|c_0|^2\lambda_1 + |s_0|^2\lambda_2$, the center of the circle;
2. $P = |c_0|^2\lambda_1 + |s_0|^2\lambda_2 - c_0s_0\delta$, in another word, $P$ is the closest point to the origin among all other points of $\mathcal{E}(\lambda_1, \lambda_2, m)$.

Without loss of generality, we may assume $|\lambda_1| \geq |\lambda_2|$. Rewrite (8) into

$$\frac{\lambda_1\lambda_2}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2 - c_0s_0\delta} = \lambda_1 \cdot \frac{\lambda_2}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2} \cdot 1 - \frac{1}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2}. \quad (11)$$

By drawing a perpendicular line from the origin to the line $\ell$, one can easily see that

$$\left|\frac{\lambda_2}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2}\right| \leq \frac{1}{\cos(\psi/2)}.$$ 

One the other hand,

$$\frac{c_0s_0\delta}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2} \leq \sin \frac{\phi}{2}.$$ 

---

1 By the elementary knowledge of triangular algebra, we know (refer to Figure 1)

$$\cos \alpha = \frac{|\lambda_3|^2 + |\lambda_1 - \lambda_2|^2 - |\lambda_1|^2}{2|\lambda_2(\lambda_1 - \lambda_2)|}. \quad (12)$$

If $\cos \alpha \leq 0$, i.e., $\pi/2 \leq \alpha < \pi$, then

$$\left|\frac{\lambda_2}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2}\right| \leq 1;$$

otherwise, $\cos \alpha > 0$, i.e., $0 < \alpha < \pi/2$, then

$$\left|\frac{\lambda_2}{|c_0|^2\lambda_1 + |s_0|^2\lambda_2}\right| \leq \frac{1}{\sin \alpha} \leq \frac{1}{\cos(\psi/2)},$$

since $\alpha \geq \pi/2 - \psi/2$. 

---
where $\phi/2 \equiv \max \{\arcsin \frac{r}{z} : r$ and $z$ is the radius and the center of a circle inside $E(\lambda_1, \lambda_2, m)\}$. Clearly

$$\psi \leq \theta, \phi \leq \theta.$$  

Hence it follows from (11) that

$$\left| \frac{\lambda_1 \lambda_2}{|c|^2 \lambda_1 + |s|^2 \lambda_2 - c s \phi} \right| \leq \frac{1}{\cos \left( \frac{\phi}{2} \right) (1 - \sin \frac{\phi}{2})} \cdot \max \{|\lambda_1|, |\lambda_2|\}. \quad (13)$$

**Theorem 3** An upper bound for $|{R}(\lambda_1, \lambda_2, m)|$ is

$$\frac{1}{\cos \left( \frac{\phi}{2} \right) (1 - \sin \frac{\phi}{2})} \cdot \max \{|\lambda_1|, |\lambda_2|\} \leq \frac{1}{\cos \left( \frac{\phi}{2} \right) (1 - \sin \frac{\phi}{2})} \cdot \max \{|\lambda_1|, |\lambda_2|\}.$$  

In the case when $E(\lambda_1, \lambda_2, m)$ is a circle, i.e., $\lambda_1 = \lambda_2 = \lambda$, we have an exactly answer:

$$|{R}(\lambda, \lambda, m)| = \frac{|\lambda|^2}{|\lambda| - m} = \frac{1}{1 - \sin \frac{\phi}{2}} \cdot |\lambda|,$$

which means the upper bound by Theorem 3 overestimates it by a factor

$$\left( \cos \left( \frac{\phi}{2} \right) \right)^{-1} \geq 1.$$  

### 3 An Application

In this section, we present an upper bound for $|F(X)|$ (refer to (2)) by simply applying Theorems 2 and 3. To this end, we assume

$$0 \notin F(A). \quad (14)$$

It follows from (14) that $0 \notin F(H) \subset F(A)$. Hence Theorem 3 applies to any ellipses inside $F(A)$ and Theorem 2 applies to $F(X)$. Let $t_1$ and $t_2$ be the two tangent lines to the boundary of $F(A)$ from the origin. Then $F(A)$ lies in the smaller sector of the complex plane divided by the two lines $t_1$ and $t_2$. Let $\theta$ be the angle of the smaller sector, and $\phi/2 \equiv \max \{\arcsin \frac{r}{|z|} : r$ and $z$ is the radius and the center of a circle inside $F(A)\}$. 

9
Theorem 4 Under the assumption of (14), we have

\[ |F(X)| \leq \frac{1}{\cos \frac{\theta}{2}(1 - \sin \frac{\theta}{2})} \cdot |F(A)| \leq \frac{1}{\cos \frac{\theta}{2}(1 - \sin \frac{\theta}{2})} \cdot |F(A)|. \]  

(15)

The inequality (15) is very pessimistic when \( \theta \) comes very close to \( \pi \). As a matter of fact, if \( \theta = \pi - \epsilon \) with \( \epsilon \) very small, one can verify that the factor before \( |F(A)| \) satisfies

\[ h(\theta) \overset{\text{def}}{=} \frac{1}{\cos \frac{\theta}{2}(1 - \sin \frac{\theta}{2})} = \frac{1}{2 \sin \frac{\theta}{2} \sin^2 \frac{\theta}{4}} \sim \frac{16}{\epsilon^3}. \]

However, if \( \theta \) is relative away from \( \pi \), the inequality (15) will give a reasonable estimate of the magnitude for \( |F(X)| \). The following table illustrates roughly how fast \( h(\theta) \) grows as \( \theta \) approaches \( \pi \).

<table>

Appendix 1: Compute the Closest Point of \( E(\lambda_1, \lambda_2, m) \) to the Origin.

We assume that (9) holds throughout.

We will not deal with the trivial case \( \lambda_1 = \lambda_2 \), i.e., \( E(\lambda_1, \lambda_2, m) \) is a circle.

In Section 2, we have learned several properties associated with the closest point of \( E(\lambda_1, \lambda_2, m) \) to the origin. Mathematically, the closest point is unique and can be found by solving certain equations. As a matter of fact, the equation to be solved eventually end up with an algebraic equation of order 4 (Two real roots of which correspond to the closest point to the origin and the furthest point from the origin, respectively; the other two roots are complex conjugates.). In this appendix, we present a numerical method based on Newton iteration to compute the closest point. (The furthest point can be computed in a similar way.) Recall that

\[ E(\lambda_1, \lambda_2, m) = \{ |c|^2 \lambda_1 + |s|^2 \lambda_2 - c \bar{s} \delta : |c|^2 + |s|^2 = 1 \} \]
by Lemma 2. A short argument will lead to

**Proposition 1** The shortest distance between the points of $E(\lambda_1, \lambda_2, m)$ and the origin is the minimal values of the function

$$f(t) = |t\lambda_1 + (1-t)\lambda_2| - 2m\sqrt{t(1-t)}, \quad 0 \leq t \leq 1;$$

and if $f(t_{\min}) = \min_{0 \leq t \leq 1} f(t)$, then the closest point $P_{clt}$ to the origin is

$$P_{clt} = f(t_{\min}) \frac{t_{\min}\lambda_1 + (1-t_{\min})\lambda_2}{|t_{\min}\lambda_1 + (1-t_{\min})\lambda_2|}.$$ 

The longest distance between the points of $E(\lambda_1, \lambda_2, m)$ and the origin is the maximal values of the function

$$F(t) = |t\lambda_1 + (1-t)\lambda_2| + 2m\sqrt{t(1-t)}, \quad 0 \leq t \leq 1;$$

and if $F(t_{\max}) = \max_{0 \leq t \leq 1} F(t)$, then the furthest point $P_{ftt}$ form the origin is

$$P_{ftt} = F(t_{\max}) \frac{t_{\max}\lambda_1 + (1-t_{\max})\lambda_2}{|t_{\max}\lambda_1 + (1-t_{\max})\lambda_2|}.$$ 

Let $t_{\min}$, $P_{clt}$ and $t_{\max}$, $P_{ftt}$ be as defined in Proposition 1. Set\(^2\)

$$b = m, \quad c = \frac{|\lambda_2 - \lambda_1|}{2}, \quad a = \sqrt{b^2 + c^2}.$$ 

The following proposition restricts the possible values of $t_{\min}$ and $t_{\max}$.

**Proposition 2** \(\frac{1}{2} (1 - \frac{c}{a}) \leq t_{\min}, \quad t_{\max} \leq \frac{1}{2} (1 + \frac{c}{a})\).

*Proof:* We give a proof for $t_{\min}$, only. As an exercise, the reader is asked to do the other. First of all, we claim the line segment joining the origin and

*With these parameters, the equation that describes the boundary of the ellipse $E(\lambda_1, \lambda_2, m)$ can now be written as*

$$|z - \lambda_1| + |z - \lambda_2| = 2a.$$
$t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2$ is perpendicular to the boundary of the ellipse at $P_{\text{clt}}$. This can be easily seen. To see what are the possible values that $t_{\text{min}}$ can take, we shall determine how big the distance between each of the two foci and $t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2$ could be. To this end, let’s perform a transformation (a shift and a rotation, generally) on the complex plane such that the foci of the ellipse are transformed to $(-c, 0)$ and $(c, 0)$, respectively. Suppose $P_{\text{clt}}$ is transformed to $(a \cos \beta, b \sin \beta)$ with $0 \leq \beta < 2\pi$. Assume, for the moment, $\beta \neq 0, \pi$. The point $t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2$ after the transformation can be located by finding the intersection of the new $x$-axis and the line passing through $P_{\text{clt}}$ and perpendicular to the boundary of the ellipse. It is easy to see that the equation of the line is

$$\frac{y - b \sin \beta}{x - a \cos \beta} \cdot \frac{b \cos \beta}{-a \sin \beta} = -1.$$  

Letting $y = 0$ gives $x = \frac{2}{a} \cos \beta$. In the other word, The point $t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2$ is transformed to $(\frac{2}{a} \cos \beta, 0)$. It is easily verified that this remains true even for $\beta = 0, \pi$. Therefore the distance between each focus and $t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2$ is between $c - \frac{2}{a}$ and $c + \frac{2}{a}$. Now, note

$$|t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2 - \lambda_1| = 2(1 - t_{\text{min}})c,$$

$$|t_{\text{min}}\lambda_1 + (1 - t_{\text{min}})\lambda_2 - \lambda_2| = 2t_{\text{min}}c,$$

from which the desired result follows.

The following proposition is easy to establish by using geometrical arguments.

**Proposition 3**

- The most general case $b > 0$ and $c > 0$:

  1. If $|\lambda_1| = |\lambda_2|$, then $t_{\text{min}} = \frac{1}{2}$, and there are two $t_{\text{max}}$ one of which lies in the open interval $(\frac{1}{2}(1 - \frac{c}{a}), \frac{1}{2})$ while the other in the open interval $(\frac{1}{2}, \frac{1}{2}(1 + \frac{c}{a}))$. And moreover the sum of the two $t_{\text{max}}$ is equal to 1;
2. If $|\lambda_1| > |\lambda_2|$, then $\frac{1}{2}(1 - \frac{c}{a}) \leq t_{\min} < \frac{1}{2}$, and $\frac{1}{2} < t_{\max} \leq \frac{1}{2}(1 + \frac{c}{a})$;

3. If $|\lambda_1| < |\lambda_2|$, then $\frac{1}{2} < t_{\min} \leq \frac{1}{2}(1 + \frac{c}{a})$, and $\frac{1}{2}(1 - \frac{c}{a}) \leq t_{\max} < \frac{1}{2}$;

- The case $c = 0$: $t_{\min} = t_{\max} = \frac{1}{2}$;

- The case $b = 0$ and $c > 0$:

1. If $|\lambda_1| = |\lambda_2|$, then $t_{\min} = \frac{1}{2}$, and $t_{\max} = 0$ and $1$;

2. If $|\lambda_1| > |\lambda_2|$, then $t_{\min} = 0$ and $t_{\max} = 1$;

3. If $|\lambda_1| < |\lambda_2|$, then $t_{\min} = 1$ and $t_{\max} = 0$.

Set $\lambda_j = x_j + iy_j$ where $x_j, y_j$ for $j = 1,2$ are real and $i = \sqrt{-1}$. Let (recall $m = b$ in (16))

$$f_1(t) = \frac{|f \lambda_1 + (1-t)\lambda_2|}{\sqrt{(tx_1 + (1-t)x_2)^2 + (ty_1 + (1-t)y_2)^2}};$$

$$f_2(t) = 2m\sqrt{t_1(1-t)}. \hspace{1cm} (17)$$

Then $f(t) = f_1(t) - f_2(t)$. Taking derivatives gives

$$f'_1(t) = \frac{(x_1 - x_2)(tx_1 + (1-t)x_2) + (y_1 - y_2)(ty_1 + (1-t)y_2)}{(tx_1 + (1-t)x_2)^2 + (ty_1 + (1-t)y_2)^2};$$

$$f''_1(t) = -\frac{[(x_1 - x_2)(tx_1 + (1-t)x_2) + (y_1 - y_2)(ty_1 + (1-t)y_2)]^2}{[(tx_1 + (1-t)x_2)^2 + (ty_1 + (1-t)y_2)^2]^{3/2}}$$

$$+ \frac{(x_2y_1 - x_1y_2)^2}{[(tx_1 + (1-t)x_2)^2 + (ty_1 + (1-t)y_2)^2]^{3/2}} > 0;$$

$$f'_2(t) = \frac{m(1-2t)}{\sqrt{t(1-t)}},$$

$$f''_2(t) = -\frac{m}{2[1(1-t)]^{3/2}} < 0.$$
From these formula it follows $f''(t) = f''_1(t) - f''_2(t) > 0$. Since $f'(t) = f'_1(t) - f'_2(t) \to -\infty$ as $t \to 0^+$, and $f''(t) = f''_1(t) - f''_2(t) \to +\infty$ as $t \to 1^-$, we see

$$f'(\frac{1}{2} \left(1 - \frac{c}{a}\right)) < 0, \quad f'(\frac{1}{2} \left(1 + \frac{c}{a}\right)) > 0.$$ 

$f'(t)$ has exactly one zero between $\frac{1}{2} \left(1 - \frac{c}{a}\right)$ and $\frac{1}{2} \left(1 + \frac{c}{a}\right)$ which is $t_{\text{min}}$.

Newton iteration can now be applied to find the point of interest. One remaining question is how to get a good initial guess. The following way is used in my MATLAB code. It is assumed $|\lambda_1| \geq |\lambda_2|$ (otherwise, simply swap $\lambda_1$ and $\lambda_2$). Then $\frac{1}{2} \left(1 - \frac{c}{a}\right) \leq t_{\text{min}} < \frac{1}{2}$. Our motivation for choosing an initial guess is based on Propositions 2 and 3 and the observation that the $t$ making $|t\lambda_1 + (1-t)\lambda_2|$ reach its minimum should be close to $t_{\text{min}}$.

Here are the formulas for $\tau$, an initial guess of $t_{\text{min}}$ (refer to Figure 1 and the equation (12)).

- If $\cos \alpha \leq 0$, set $\tau = \frac{1}{2} \left(1 - \frac{c}{a}\right)$;
- If $\cos \alpha > 0$, set $\tau = \frac{\lambda_2 \cos \alpha}{2c}$.

Appendix 2: The Tangent Lines of the Ellipse $E(\lambda_1, \lambda_2, m)$ from the Origin.

Let the assignments to $x_j$, $y_j$, $a$, $b$ and $c$ in Appendix 1 hold throughout this appendix. Assume also (9) holds throughout. The slopes $k$ of the two tangent lines from the origin to the boundary of the ellipse are the roots of the following algebraic equation of order 2:

$$[(4a^2 - (x_1 + x_2)^2 - (y_1 - y_2)^2)k^2 + 4(x_1y_2 + x_2y_1)k + [(4a^2 - (x_1 - x_2)^2 - (y_1 + y_2)^2)] = 0. \quad (19)$$

A by-product of this is that the assumption (9) holds if and only if (19) has real solutions.
Appendix 3: Some Typical Graphs for $\mathcal{R}(\lambda_1, \lambda_2, m)$.

This appendix displays four graphs Figures 2–5 for $\mathcal{R}(\lambda_1, \lambda_2, m)$ in different situations. They are telling us what a typical $\mathcal{R}(\lambda_1, \lambda_2, m)$ looks like.
